

Ex 11

objects

1) To form the enolate we need to have an α -proton. It's C-H bond must allow for overlap with the $\pi^*_{C=O}$ and the resulting $C=C$ must be stable

does not have an α -proton

does have α -protons, but they have no overlap with $\pi^*_{C=O}$

strained ring that does not comply with Bredt's rule

2) let's apply the same logic here

H_a has good overlap

H_b not

$\Rightarrow H_a$ more acidic

3) Here two things are important: ① Dipole ② H-Bonds

Eq. on left bc with the formation of the H-Bond we create a larger dipole.

- conjugated structure

- H-bond

- weaker dipole

forced cis conformation of α -diketones

4

bc charge is neutralized

- amine better donor than alcohol

- \oplus stabilized by methyl groups

5)

thermodynamic

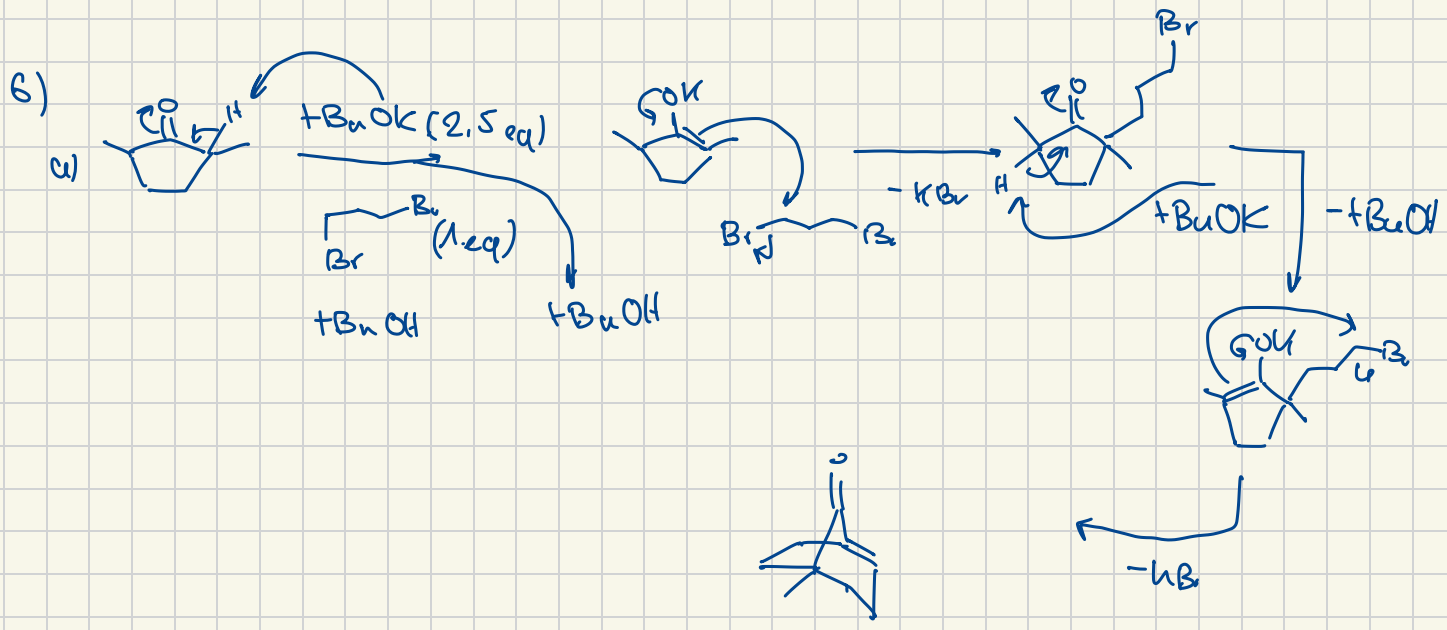

- reversible endate
- weak base
- forms more stable molecule

↓
Saytzeff rule

more substituted DB
more stable

kinetic

- irreversible, with strong base
- **Low temp**
- less stable endate
- * Deprotonation of more accessible α -proton
